Abstract

1
2
3 The calcareous tube of *Pomatoceros* is one of the most highly studied serpulid
4 dwelling tube-structures. Despite this, there is a lack of consensus regarding the
5 number and types of fabric within the tube structure, and the three-dimensional
6 distribution of the fabrics about the tube. These are here described in *Pomatoceros*
7 *triqueter* within the coastal waters of Britain, with lamello-fibrillar, irregularly
8 oriented prismatic and spherulitic-prismatic fabrics noted as the major ultrastructural
9 components. Fabrics are distributed along a chevron-shaped growth lamella structure,
10 passing progressively from lamello-fibrillar fabric on the inner part of the tube, to
11 irregularly oriented prismatic fabric along the outer part. This model can be
12 adequately applied to all previous descriptions of the ultrastructure of *Pomatoceros*.
13
14 All analysed samples comprise Mg-calcite, with typically 10-15 mol% MgCO₃.

1. Introduction

Pomatoceros Philippi, 1844, is a common extant serpulid that forms a calcareous-tube, which has a roughly ‘triangular’ cross-section, with an axial ridge developed along its upper surface. *Pomatoceros* has recently been assigned to *Spirobranchus* de Blainville, 1818, by a number of authors (Pillai, 2009; Vinn et al., 2009). However, material from the temperate waters of the North Atlantic, is still commonly assigned to *Pomatoceros*, and have been described historically as such by a number of authors (Bianchi, 1992; Campbell and Nicholls, 1994; Vinn and Zaton, 2012; Weedon, 1994). Here we follow ten Hove and Kupriyanova (2009), and retain *Pomatoceros*.

The tube of *Pomatoceros* has been described by a number of authors (Hedley, 1958; Vinn et al., 2009; Weedon, 1994), with Weedon (1994) and Vinn et al. (2009) detailing aspects of tube ultrastructure. Details concerning the presence and distribution of fabrics differ between the published papers and the current work. This paper aims to reconcile these anomalies, by unification under a new model based upon the present study. The tube structure of *Pomatoceros triqueter* (Linnaeus, 1758) is therefore described at a macro- to ultrastructural level, using a range of materials collected throughout the British Isles.

2. Material and methods

In excess of twenty-five individual samples were prepared and examined, from localities around the British Isles. This material can be assigned to *P. triqueter* based on the illustrations and description of Bianchi (1992).

1 Materials were analysed using an FEI Quanta 650 FEG ESEM, a Phillips XL30 LaB₆
2 ESEM and a Hitachi S-4100 FEG SEM.
3

4
5 Both natural and broken surfaces were examined, as well as samples impregnated in
6 resin and examined as polished blocks or thin-sections. Some samples were treated
7 with a 5% solution of bleach, or dilute (1.5%) HCl acid. Polished blocks and thin-
8 sections were also examined using MAPSTM an automated image acquisition and
9 stitching programme (see Buckman, 2014).
10
11

29 3. Results 30

31
32 The tube structure of *P. triqueter* can conveniently be considered at three levels:
33 macro-, micro- and ultrastructural.
34
35
36
37

38 3.1. Macrostructure 39

40
41 Tubes typically in the region of 3 mm wide. Triangular in transverse section (Fig.
42 1A), with a well-developed axial ridge, which protrudes beyond the aperture (Fig.
43 1A), with a well-developed axial ridge, which protrudes beyond the aperture (Fig.
44 1B). Mature specimens exhibit a thickening of the aperture to give the appearance of
45 a collar (Fig. 1B). Encrusting surfaces, with base exhibiting a cellular alveolar
46 structure (Fig. 1A), which are 200-500 µm in size, and vary in shape from irregular to
47 lunate. A perforated tabulae ('grating') is occasionally observed towards the distal
48 end of the tube (Fig. 1G). Specimens occur either individually, attached directly to a
49 variety of substrates, or as tortuous masses of twisted individuals in knotted

‘spherical’ agglomerations. In some rare cases, a substantial section of the tube can be lifted up from the surface, although this is generally rare.

Pomatoceros triqueter has a calcified operculum, in the form of a convex disc or inverted cone, with variably developed tripartite horns at the apex (Fig. 1E, F).

3.2. Microstructure

The tube of *P. triqueter* comprises two types of layer, the chevron layer, and the pseudo-laminar layer (Fig. 1A, C, D, 2), of which the former is usually quantitatively the more important. The pseudo-laminar layer is the attenuated distal extension of the chevron layer, occurring on the outer surface of the tube. The boundary between the two is usually sharp and relatively straight, but may also be undulatory (Fig. 1C, D), typically having an unconformable angular relationship.

Both layers are composed of individual growth lamellae, which form either simple sheet-like structures, or lens-shaped pods and are clearly chevron-shaped with their apex directed towards the aperture (Fig. 1C, D, 2).

Organic membranes are commonly observed, especially in the chevron layer (Fig. 1C, D).

3.3. Ultrastructure

Three main styles of fabric can be recognised within the main tube: lamello-fibrillar, irregularly oriented prismatic, and spherulitic-prismatic. Additionally a lozenge fabric and a platey fabric occur but to a limited extent. Lamello-fibrillar and irregularly orientated prismatic fabrics represent the dominant style of ultrastructure.

3.3.1. Lamello-fibrillar fabric

1 Forming wedge or lens shaped lamellae that are typically 0.97 - 12.56 μm thick
2 (average 4.63 μm , $n = 61$). Comprising individual lath-shaped elements that are
3 oriented parallel or sub-parallel to each other, and occur at a low angle to, or parallel
4 to, growth lamellae (Fig. 3A). Between successive lamella, laths are typically oriented
5 in different directions, at up to 90° from laths in the previous lamella (Fig. 3A).
6
7 Individual laths are 145 - 776 nm wide (average 381 nm, $n = 315$) by several microns
8 in length.
9

10 3.3.2. Irregularly oriented prismatic fabric

11
12 Comprising lath-like structures, with dimensions of 152 - 725 nm wide (average 363
13 nm, $n = 296$) by several microns in length. Laths are arranged in a completely
14 unordered chaotic fashion, which displays no preferred orientation with respect to
15 growth lamellae (Fig. 3B). Laths are commonly loosely packed, with lamellae having
16 a porous appearance. Fabric is massive in appearance, with occasional hint of
17 lamellae in the range 2.34 - 24.40 μm (average 7.04 μm , $n = 29$).

38
39

40 3.3.3. Spherulitic-prismatic fabric

41
42 Fine needle-like crystallites in the order of 34 – 99 nm wide (average 54 nm, $n=87$) by
43 3.86 – 16.89 μm or more in length (average 10.79 μm , $n=20$), occurring in micron
44 sized bundles (Fig. 3C). Crystallites approximately perpendicular to growth lamellae,
45 and exhibit a fan-like morphology (Fig. 3C, D), botryoidal appearance on growth
46 surfaces (Fig. 3G). Individual crystallites continuous across minor growth lamellae.
47
48 Occurring in lamellae of about 1 to 5 μm thick, but also in lenses up to 30 - 50 μm
49 thick.

60
61
62
63
64
65

3.3.4 Lozenge fabric

1
2
3 Lozenge shaped 'crystals' (Fig. 3G, H), with both ends tapering, 379 - 811 nm wide
4
5 (average 679 nm, n = 27), by 1.160 - 2.494 μm long (average 2.379 μm , n = 27). The
6
7 latter are observed along the skirt at the front of the tube, and occur above a thick
8
9 organic lamella, from which they appear to originate (Fig. 3G). Substructure
10
11 uncertain.
12
13

3.3.5. Platey fabric

14
15
16
17
18
19 The tabulae (Fig. 1G) comprise flat platy crystals, with well-formed crystal
20
21 terminations. Crystals occur radially, but with no specific preferred direction of
22
23 growth (Fig. 1H).
24
25

3.3.6. Organic membranes

26
27
28
29
30
31 Organic membranes are occasionally observed between and within inorganic lamellae
32
33 (Fig. 3E) of all three of the major fabrics. The structure of the organic layers often
34
35 appears homogeneous. However, on rare occasions they are observed to have a
36
37 fibrous structure (Fig. 3F), or appear as a fine meshwork (Fig. 3D). The latter may be
38
39 due to degradation. The base of an organic membrane is often gradational in nature,
40
41 while the upper surface is generally sharp.
42
43
44
45
46
47
48
49

3.3.7. Variation in fabric distribution

50
51
52
53 The fabric of the chevron lamellae change from inner to outer margin, in a
54
55 progressive and predictable fashion, which is herein termed 'differentiated chevron
56
57 structure'. Lamello-fibrillar fabric occurs along the inner surface, and irregularly
58
59
60
61
62
63
64
65

1 oriented prismatic along the outer, with the change occurring approximately at the
2 apex of the chevron (Fig. 2). The change either takes the form of tapering lamellae
3 comprising lamello-fibrillar fabric, or a gradual passage from lamello-fibrillar to
4 irregularly oriented prismatic fabric along an individual lamella.
5
6
7
8
9

10 Spherulitic-prismatic fabric occurs along the inner margin of the tube, where it is
11 interleaved with lamello-fibrillar fabric, and has a growth vector in an inwards
12 direction (towards the lumen). This fabric also occurs as the infill to irregular shaped
13 pods (within the pseudo-laminar and chevron layers), as well as a lining within the
14 cavities of alveoli. Additionally the fabric is particularly common near the aperture of
15 mature specimens.
16
17
18
19
20
21
22
23
24

25 3.3.8. Operculum fabric

26 Opercula horns are often hollow, and after treatment with bleach solution, the tips can
27 often disappear. The dominant fabric within opercula is a fibrous texture, with a
28 granular sub-structure (Fig. 4A), with fibres in the order of 500 nanometres in width.
29 Fibres are generally arranged radially (including within the horns), starting at the
30 outer surface and orientated inwards, although also seen to be oriented parallel to
31 opercula outer surface (Fig. 4B). On both external and internal surfaces, bundles of
32 fibres are often constrained within polygonal packages (Fig. 4C, D). A more granular
33 texture is sporadically observed, with granules rounded and approximately 500
34 nanometres or less in size (Fig. 4E). Spheroidal structures (30 to 50 microns wide)
35 are also noted to occasionally occur near the outer surface (Fig. 4F). The tripartite
36 horns and outer part of opercula are often densely pervaded by sinuous hollow tubes
37 that run parallel to the outer surface of the opercula (Fig. 4G). These tubes are lined
38 by radial masses of acicular or blade-like crystals (Fig. 4H). The inner surface of the

1 opercula can be covered by low mounds, in the order of 5 to 50 microns in width (Fig.
2 4D).
3

4 3.4. Composition 5

6 3.4.1. Tube composition 7 8 9

10 The occurrence of Mg-calcite was indicated by EDX analysis. All eight samples
11 analysed by powder XRD, gave d_{104} values of between 2.99 and 3.01, indicating a
12 Mg-calcite composition, with between 10 and 15 mol% $MgCO_3$ (Table 1).
13
14
15
16
17
18
19

20 3.4.2. Operculum composition 21

22 Analysis by EDX indicates that opercula are composed of calcium carbonate. Small
23 amounts of Mg (1.8 wt%) are observed from the outer surface of the opercula,
24 between the tripartite horns, otherwise the majority of the opercula lack any Mg
25 content, but possess significant amounts of Sr (0.2 wt%); suggesting that opercula are
26 formed from aragonite.

32
33
34

35 4. Discussion 36

37 4.1. Structure and distribution of fabrics 38 39

40 The fabric distributions determined here differs in detail from that of previous
41 workers (Vinn et al., 2009; Weedon, 1994). Weedon (1994) recognised an overall
42 chevron-shaped structure to the tube of *P. triqueter*, which was composed of an
43 ordered chevron fabric (= lamello-fibrillar fabric), and the localised occurrence of
44 unordered chevron fabric (= irregularly oriented prismatic fabric) towards the outer
45 margin of the tube, although not illustrating this within his three-dimensional model
46 (Weedon, 1994: fig. 2). Although Weedon (1994) recorded spherulitic-prismatic
47

63
64
65

1 fabric within *Spirorbis*, it was not noted from *Pomatoceros*. Vinn et al. (2009)
2 described two fabric types in *Pomatoceros americanus* Day, 1973; lamello-fibrillar
3 structure on the inner margin, and irregularly oriented prismatic structure along the
4 outer parts of the tube. No mention was made of a chevron structure, although Vinn
5 had previously illustrated a chevron structure to the tube of *P. triqueter* (Vinn and
6 Zaton, 2012: fig. 8). Vinn et al. (2009) did not note the presence of spherulitic
7 prismatic fabric within *P. americanus*. In addition, Vinn et al. (2008: table 2) and
8 Vinn (2013: table 1) indicate that *Spirobranchus* / *P. triqueter* (from Sweden) only
9 has lamello-fibrillar fabric.
10
11
12
13
14
15
16
17
18
19
20
21

22 Given the present observations, and those of the above mentioned authors, it is clear
23 that the tube structure of *Pomatoceros* should be thought of in terms of a series of
24 stacked simple chevron-shaped growth lamellae, in which the distal extremities on
25 the outer margin of the tube are occasionally greatly attenuated away from the
26 aperture, giving the appearance of an outer tube parallel laminar layer (the pseudo-
27 laminar layer) (see Fig. 1A, C, D, 2). Ultrastructurally, the inner tube margin
28 comprises a lamello-fibrillar fabric (ordered chevron structure of Weedon, 1994),
29 passing into irregularly oriented prismatic fabric (unordered chevron fabric of
30 Weedon, 1994), at about the apex of each chevron (Fig. 2); forming a ‘differentiated
31 chevron’ structure. Additionally, minor developments of spherulitic-prismatic fabric
32 can be sporadically observed at a variety of locations (Fig. 2). Given the Swedish
33 material of Vinn (2013), and the comments of Weedon (1994), it is likely that both
34 irregularly oriented prismatic fabric and spherulitic-prismatic fabrics are variable in
35 occurrence within *Pomatoceros*.

54
55

56 4.2 Comparison of opercula 57 58 59 60 61 62 63 64 65

1 The opercula of *Pomatoceros* is not often described, with a notable exception being
2 that of Vinn and ten Hove (2011) describing the opercula of *Spirobranchus giganteus*
3 (*Pomatoceros* belonging to *Spirobranchus* according to Pillai (2009) and Vinn et al.
4 (2009)). The opercula of *Pomatoceros triqueter* differs from that of *S. giganteus* in a
5 number of major points. Firstly, *P. triqueter* has simple tripartite horns (sometimes
6 vestigial), as opposed to well-developed antler-like horns. Secondly, there is no sign
7 of an outer layer of irregularly ordered prismatic (IOP) fabric within *P. triqueter*.
8 Thirdly, *S. giganteus* exhibits a plethora of large pores (~10 micron wide), clearly
9 observed on the outer surface, that pass vertically through the opercula. Whereas, *P.*
10 *triqueter* has 5-10 micron diameter sinuous hollow tubes that are parallel to the
11 opercula outer surface, and restricted to the outer layer. The fibrous fabric observed
12 within *P. triqueter* bears some similarity to elements of the irregular spherulitic
13 prismatic structure from the opercula of *S. giganteus*, as well as the regular spherulitic
14 prismatic structure within the opercula of *Pyrogopolan ctenactis* (see Vinn and ten
15 Hove, 2011: fig. 4). The polygonal packaging of fibres within *P. triqueter* in
16 particularly resembles the regular spherulitic prismatic structure from *Pyrogopolan*
17 *ctenactis* (see Vinn and ten Hove, 2011: fig. 1d-f, 2c,d), although no organic
18 membrane was detected from the current study. Further investigation of the fibrous
19 fabric within the opercula of *P. triqueter* is warranted, although beyond the scope of
20 the present paper.

21 The disappearance of the tips of horns from opercula is of importance, as this suggests
22 a high organic content and compares to the situation with the opercula horns of
23 *Pyrogopolan ctenactis* (Vinn and ten Hove, 2011).

24 The fibrous fabric observed within the opercula of *P. triqueter* is similar in many
25 respects to the spherulitic prismatic fabric observed within the co-associated tubes,
26
27

1 the main difference being its apparent aragonitic composition as opposed to the Mg-
2 calcite found within the tube. The occurrence of a Mg-calcite precursor layer in the
3 opercula is therefore extremely important, indicating that the form of calcite produced
4 can be readily switched, having implications on the relationship between this fabric
5 between opercula and tube. It is possible that the mechanisms / organs responsible for
6 the formation of both are the same, which is worthy of future investigation.
7
8
9
10
11
12
13

14 4.3. Composition

15
16 The tubes of *P. triqueter* analysed herein are all Mg-calcite, with powder XRD d_{104}
17 values indicating between 10-15 mole % MgCO_3 (Goldsmith & Graf, 1958: table 5;
18 Hardy and Tucker, 1988; Zhang *et al.* 2010: fig. 6). No peaks for aragonite were
19 observed from the tubes. Samples were also analysed by EDX to determine the
20 presence or absence of strontium, as the latter element can be taken as a proxy for
21 aragonite (Taylor *et al.*, 2010); however, no strontium was observed, from EDX
22 analysis of the tubes, suggesting that the samples analysed only comprised Mg-
23 calcite. The composition of many described samples of *Pomatoceros* from the
24 literature are typically not given. One French sample of *P. triqueter* (from Marseille)
25 is described as comprising 31% aragonite and 12.5 mol% MgCO_3 (Bornhold and
26 Milliman, 1973: table 1). Such differences may be a factor of temperature (see
27 Bornhold and Milliman, 1973). The samples from the present study are consistent
28 with the range of compositions previously recorded for *Pomatoceros*. The
29 distribution of mol% MgCO_3 values (Table 1) appears to show a general correlation
30 with geographical distribution (latitude), with a trend towards increasing mol%
31 MgCO_3 with higher latitudes; suggesting a possible link with water temperature.
32 However, the most northerly sample also has one result the same as the most
33 southerly. The latter may be spurious, although it should be noted that *Pomatoceros*

1 recorded from Marseille does not fit this trend either (Bornhold and Milliman, 1973:
2 table 1). No specific data regarding water temperature, or other factors such as water
3 depth were collected, therefore water temperature (latitude) may not be the main
4 controlling factor for composition. This agrees with recent work, suggesting that
5 serpulid tube composition may be controlled phylogenetically rather than by
6 temperature (see Smith et al., 2013).

15 The aragonitic composition of the opercula is of interest, as it substantiates the ability
16 of *Pomatoceros* to utilize aragonite during biomineralization, indicating that this is
17 not just restricted to examples from warmer waters such as the Mediterranean Sea
18 (see Bornhold and Milliman, 1973). The apparent lack of aragonite from the tube and
19 the virtual 100% composition from the opercula requires further study, to elucidate
20 the mechanism and origin of these differences.

30 4.4. Importance of organic layers 31 32

33 Vinn (2013) discussed the presence and significance of organic layers within serpulid
34 genera, including *Spirobranchus triqueter* (= *P. triqueter*), where organic membranes
35 were commonly associated with lamello-fibrillar fabric. The organic layers herein
36 associated with lamello-fibrillar fabric appear to gradually form towards the end of
37 deposition of a lamella, and form a sharp base for the next; they do, however, not
38 terminate every lamella. This supports the findings of Vinn (2013). In the case of
39 spherulitic-prismatic fabric, growth can be initiated along an organic membrane (Fig.
40 3D), with the membrane having a potential controlling role in the initialisation of
41 mineral deposition. A close relationship is also suggested by the association of
42 membraneous organic material within spherulitic-prismatic fabric. With irregularly
43 oriented prismatic fabric, the relationship with organic material appears simpler,

1 forming a bulking agent for the randomly oriented lath like crystals. Analysis of the
2 amino acid composition of such organic membranes would likely prove of interest in
3
4 determining the relationship between organic membranes and calcite crystals.
5
6

7 8 5. Conclusions 9

10
11 *P. triqueter* has an interesting tube ultrastructure comprising lamello-fibrillar and
12 irregularly oriented prismatic fabrics distributed across chevron-shaped lamellae.
13
14 Lamello-fibrillar fabric occurs along the inner tube margin, changing to irregularly
15 oriented prismatic fabric from about the inflection of the chevron. Irregularly oriented
16 prismatic fabric on the outer surface can become greatly attenuated distally,
17
18 developing a ‘pseudo-laminar’ layer. In addition, variable amounts of spherulitic-
19 prismatic fabric can occur throughout the tube of *P. triqueter*, although this is not
20 generally significantly developed. This pattern in ultrastructure distribution is typical
21 of *Pomatoceros* in general, although all elements may not always be developed to
22 such an extent. In the case of some *P. triqueter* tubes, ultrastructure may be restricted
23 to lamello-fibrillar fabric (see Vinn, 2013).
24

28
29
30
31
32
33
34
35
36
37
38

39 The tube of *Pomatoceros* can vary from Mg-calcite to aragonite, although in the
40 present study all samples were 100% Mg-calcite, and typically ranged between 10 –
41
42 15 mol% MgCO₃.
43
44
45
46

47 The nature and distribution of organic lamellae within *P. triqueter* agree with the
48 findings of previous authors (Vinn, 2013).
49
50
51
52

53 The opercula are predominantly aragonite, with a fabric similar to irregular spherulitic
54 prismatic and regular spherulitic prismatic structures within the opercula of other

65

1 annelids (see Vinn and ten Hove, 2011). Further study is likely to yield data of
2 taxonomic significance.
3

4
5 The current work demonstrates the value of automated image collection and stitching
6 software, such as ‘MAPS’, as it allows for high-resolution study of fabrics
7
8 continuously over large areas, helping to clarify the nature of fabric distribution
9
10 across the whole tube.
